The Hypogonadism in Males (HIM) Study found that prevalence of low testosterone in men increases with age, ranging from 38% in the 45-54 years age group to 58% in men over 65 years. Incremental associations with increased body mass index (BMI), diabetes and cardiovascular disease.**

A study of the prevalence of low testosterone rates, based on a large, nationwide database, may help reveal new insights on the population of men affected by this condition.

**Comorbidities associated with low testosterone are obesity (increased body mass index), diabetes and cardiovascular disease.

**A study of the prevalence of low testosterone rates, based on a large, nationwide database, may help reveal new insights on the population of men affected by this condition.

Based on a nationwide laboratory results database, the HIM Study found that prevalence of low testosterone in men increases with age, ranging from 38% in the 45-54 years age group to 58% in men over 65 years. Incremental associations with increased body mass index (BMI), diabetes and cardiovascular disease.

Comorbidities associated with low testosterone are obesity (increased body mass index), diabetes and cardiovascular disease.
